

Where genomes fall one step short of a GIFT

A near miss is an unsupported GIFT whose closest implementation lacks exactly one of at least two requirements: 11,736 of 81,599 unsupported calls.
a: phyla with at least 5 genomes, ordered by median size deviation. b: the 30 requirements most often missing alone (genomes in brackets).

A near miss is never counted as support. A requirement missing across a lineage is a candidate for an uncurated alternative, or for a capability the lineage does not encode; the table ranks candidates and decides nothing.
